## Table of Contents

<b>Subject Discussed</b>	<b>Addendum Page</b>
Why an addendum?	1
<b>Chapter 12</b>	
Mutations - p.304	1
<b>Chapter 15</b>	
What is Evolution? - p.369	5
Evolution by Natural Selection - p. 380	5
Homologous Structures - p. 384	6
Vestigial Structures - p. 385	7
Similarities in Early Development - p. 385	7
<b>Chapter 16</b>	8
<b>Chapter 17</b>	
Fossils and Ancient Life - p. 417	8
Earth's Early History and The Origin of Life - p. 421	9
Early Atmosphere - p. 423	11
The Miller Experiment - p. 424	12
RNA Chain Formation - p. 425	13
Polymers Evolve - p. 421	13
The Unbreakable Cycle	14
Cambrian Fossils - p. 430 and 746	14
Dinosaur to Bird Evolution - p. 432 and 807	14
Macroevolution - p. 435	15
Punctuated Equilibrium - p. 439	15
Developmental Genes and Body Plans - p. 440	15
<b>Chapter 32</b>	
Human Evolution - p. 834	16
Conclusions	17

## Why an Addendum?

An addendum is necessary because the authors have written the text around the idea that evolution is an essential part of biology. It should be remembered that biology is the study of living things. It is not necessary to know about an organism's origin: to determine how it functions internally and externally, to how it relates to other organisms and to make predictions about other organisms. Origin of and similarity to other organisms, while interesting, is not necessary to understand the detail functioning of a specific organism.

The term evolution has more than one meaning which leads to many misunderstandings and unsupported conclusions. Sometimes “evolution” means evidence for small-scale changes within species which we can observe in the present day. At other times, claims of “evolution” are based upon extrapolation and speculation about the deep past. Read the first section on Chapter 15 of this addendum (page 4) for an understanding of the problem

This presentation will provide additional facts concerning evolution so that the student can clearly see problems not answered by the theory of evolution. This addendum presents facts that the student should consider when judging the soundness of the theory of evolution.

Should the student learn about the theory of evolution? Definitely! It is the dominant thinking of today in the fields related to biology.

This paper presents information only on the sections of the text where it is felt that additional information would be helpful. The information is presented as simply and briefly as possible since time is crucial in the classroom. Reference to the textbook will be necessary to completely understand this material.

## Chapter 12 Mutations Page 307

In order to properly understand the process by which organisms change and its implication regarding the theory of evolution it is necessary to review this section from Chapter 12 and to read the next two sections of this addendum.

The text defines a mutation as “*changes in the DNA sequence that affect genetic information.*” Recognize that the definition concerns changes in genetic information but that “new information” must be added to the DNA in order to build complexity in organisms. The question to keep in mind is, “**Does the mutation actually increase the information contained in the DNA or decrease it.**” An increase in information is necessary to claim that microorganisms eventually evolved into higher organisms like humans. It is essential that this need for information be understood. Did the transition from the conventional cars of today to the hybrid cars require additional coherent information or is the hybrid car simply a rearrangement of the information required to build a conventional car? Yes, information had to be added.

The rest of chapter 12 discusses different mutation mechanisms and forces that cause changes in genes and therefore changes in organisms. It must be remembered that just because mutational changes do occur at the species level this does not prove that all organisms descended from a common ancestor. The textbook does not discuss some of the factors that give the reader an understanding of how difficult speciation is and the fact that it cannot explain the phenomena of molecules to man or even amoeba to man evolution.

First of all it must be remembered that the DNA in a living organism contains the complete information necessary to form an identical organism including the instructions of how to make a reader for its own code system. The amount of information stored in the DNA is staggering. Second, the amount of information stored in the DNA of man is 4166 times more than that of the H-39 Mycoplasma - one of the smallest bacteria which is now called a mollicute.<sup>1</sup> To put this in perspective the mollicute (H-39 mycoplasma) DNA (768,000 base pairs)<sup>2</sup> has the amount of information contained in the first 21 chapters of this

text if every page were covered by nothing but print with **no** pictures, graphs or headings similar to this typed page. The information content in the DNA of man (3.2 billion base pairs)<sup>3</sup> is the same as 527 books like this text with **nothing but text** on the pages as just described. Some might argue that the above numbers are highly exaggerated because of what some call “junk DNA” but it is now known that the so called “junk DNA” is not junk. It is made up of introns, promoters, terminators and telomeres<sup>4</sup> which are functional parts of the DNA. These authors mention introns and telomeres on p. 302 as having functions. A major question is where did all of this additional information come from to fill the 526½ additional books?

To understand the problem consider the following. There is no known mutational mechanism that will increase the information content of DNA in a **meaningful** manner. In other words, transposons, point and frameshift mutations, duplication errors, jumping genes, extra chromosomes, and viral or bacterial invasion do not add **meaningful** information to the DNA. Viral or bacterial invasion may add information but the chances of it being **meaningful** is zero if it occurs **in a random manner**. Think about this problem with respect to this textbook. Does mixing sentences, letters, paragraphs, errors in copying, mixing up chapters or adding two or more identical chapters add information? The textbook may contain more pages but does it contain more information? No! It is inconceivable that **meaningful** information can be added to accomplish the bacteria to man requirement of evolution by random chance happenings particularly when the number of times it must happen and the fact that it must occur in the cell that will be involved in reproduction is considered. It should be recognized that natural selection may decrease the information in DNA but it cannot increase it

**Think Critically:** It has been discovered that the largest bacteria *Epulopiscium fishelsoni* has 85,000 copies of one of its genes and contains approximately 25 times as much DNA as a human cell.<sup>5</sup> Does this confirm the need for added DNA to be meaningful?

. It is hypothesized that these changes in species ultimately lead to changes at the genus level, the family level and on up to the kingdom level. The great complexity and preciseness found in the DNA and the tremendous increases in DNA information content necessary to evolve from “amoeba to man” make the hypothesis unlikely. When duplication errors, favorable mutations rates and the time necessary to establish a trait are considered this becomes apparent.

It is known that duplication (replication) errors are extremely rare. There is no more than one error in 1,000,000,000 base pairs when copying the DNA. The textbook “Biology: The Dynamics of Life” by Biggs, Kapicka and Lundgren (Glencoe, 1995) further complicates the problem when it makes the following statements, “*Sometimes, there is no effect on an organism, but often mistakes in DNA can cause serious consequences for individual organisms*” (p.324). “*Sometimes, the errors caused by point mutations don’t interfere with protein function, but often the effect is disastrous.*” (p.325) “*Proteins that are produced as a result of frameshift mutations seldom function properly.*” (p.325) “*Few chromosome mutations are passed on to the next generation because the zygote (several cells beyond conception) usually dies.*” (p.326) “*Mutations often result in sterility or the lack of normal development in an organism.*” (p.328) Other authors comment that only about one in 1000 mutations “might” be beneficial.<sup>6</sup> Generally it takes about 5 mutations to make a significant physical change in an organism.<sup>6</sup> Note that this does not mean a new species has been formed. Many more than five mutations at a time have been caused on fruit flies [*Drosophila melanogaster*] with only a deformed fruit fly as a result. Dodson proposes that it takes over 300,000 generations for a slightly beneficial recessive gene to increase in frequency from 1 in 1,000,000 to 2 in 1,000,000.<sup>7</sup> **It must also be remembered that a mutation in any cell other than the reproducing cell does not have any influence on succeeding generations.** When all of these probabilities are combined, the question must be asked, “How can macro evolution occur from processes that produce many more negative results than positive results?”

with an arch like humans have, how long will it take to establish a small population of apes with arched feet? This ape will mate with one who does not have the same gene and, according to Mendel's laws of heredity, probably will not have an offspring with the same characteristic. It will be quite a few generations of inbreeding before this trait will begin to show up with any regularity unless the apes with the arched feet gene only mate with each other. This is very unlikely. If a mutation could become dominant in 10 years (an actual impossibility for members of the ape family) and there are 150,000,000 mutations required to result in man (see section on Human Evolution on page 16 of this addendum) then 300 million years would be needed under very unusual and unique conditions for man to have come from the ape family. Not nearly enough time has elapsed to have established a small population of man under this condition since evolutionists claim that the supposed ancestor of modern man came on the scene about 4 million years before man. If the number of mutations, the small probability of a beneficial mutation and the difficulty of establishing a population are all considered, it is inconceivable that man could have evolved from the ape.

Each one of the arguments discussed in the previous paragraphs indicates the macro evolution of man is not a reasonable assumption. When all three are considered at the same time it should be apparent that macro evolution is an impossible scenario.

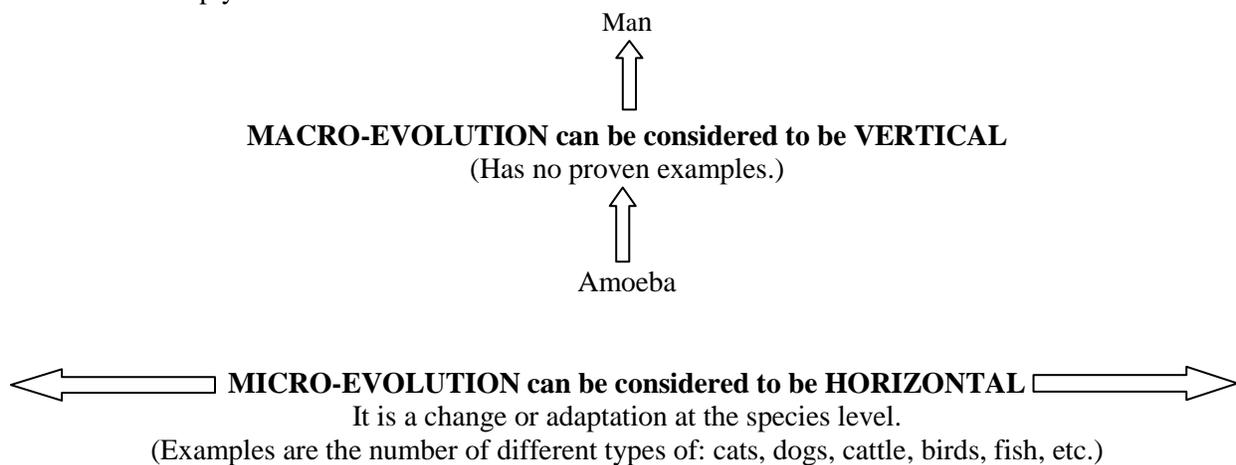

Examples of mutational changes are particularly instructive when it comes to the evolutionary concept. Mice living at the Chernobyl reactor show mutational changes but they and their offspring are still mice. With all the thousands of mutational experiments carried out on the fruit fly (*Drosophila melanogaster*), where the mutational rate was increased by 15,000 percent<sup>10</sup>, none have produced a better fruit fly nor anything other than a fruit fly that survived and reproduced. In fact, an interesting experiment was carried out in 1948 by Ernst Mayr and reported by J. Rifkin<sup>11</sup> that revealed mutations can cause only a limited variation in a species. Starting with a parent stock that had 36 bristles the fruit fly was selectively bred (not a random event) in an attempt to have a fruit fly with no bristles. After 30 generations the number of bristles was lowered to 25 but then the line became sterile and died out. A second experiment was carried out to increase the number of bristles. Once again sterility set in when the number of bristles reached 56. Mayr concludes "*The most frequent correlated response of one-sided selection is a drop in general fitness. This plagues virtually every breeding experiment.*" This addendum's author can confirm this from his experience in raising peaches commercially. The peach trees that produce the prettiest and largest peaches will quickly die if not cared for. This is in direct contrast to wild trees that are seen flourishing around an old abandoned house for years without care. The selective crossbreeding of trees for large fruit with good flavor weakens the ability of the tree to survive. What does all of this mean? It means that when man deliberately introduces mutational changes into the DNA, the probable result is an organism that is not as environmentally adept at coping with the environment as it could originally. Why should an organism be stronger when undergoing random mutations if "controlled" mutations do not do the job?

## Chapter 15

### What is Evolution? Page 369, line 9

The textbook authors say “*Evolution, or change over time, is the process by which modern organisms have descended from ancient organisms.*” This definition is so broad that it will cause confusion between the various aspects of this unit unless it is discussed and more accurately defined. If this is the definition of evolution then certainly it has occurred since things have changed and are changing. However, in today’s world this definition is very misleading. As you will learn in Chapter 15, Charles Darwin observed that species change and adapt to their surroundings. He observed that natural selection was a very strong driving force that can and does cause these kinds of changes. He then assumed that these small changes meant that all living organisms could be accounted for through this adaptive process. Wherein this assumption is held by many scientists there is a large number that do not agree with Darwin’s assumption. Because of this the term evolution has been broken down into the terms micro-evolution (meaning adaptation) and macro-evolution. Darwin observed the ability of organisms to adapt (micro-evolution) and assumed that on this basis macro-evolution was true. The textbook defines macro evolution as “*large scale evolutionary changes that take place over long periods of time.*” (Page 435) Macro-evolution could be said to occur if a dog became a cat or a dinosaur became a bird. It occurs at the genus or higher level (see page 448) and implies that all life on Earth descended from a few types of cells that somehow came into being in the past. Many scientists do not agree with this hypothesis. The diagram below should help you to understand the differences.

Based upon these definitions it is easy to see that micro-evolution is true but the truth of macro-evolution has not been established. Using the term "evolution" without specifying which type is being discussed is obviously misleading and unfortunate and has caused much misunderstanding among scientists and the public. The term “macro” or “molecules to man” evolution should be used in order to clarify the problem. It will be used from this point on in this addendum. A special definition of science must be formulated in order to assert that the general term “evolution” is science unless it is broken down into its two parts micro and macro evolution. Micro evolution is science but macro evolution is not.

### Evolution by Natural Selection Page 380-382.

It has already been established that the complete description of an organism is contained in its DNA. In order for a macro evolutionary step to take place meaningful information has to be added to the DNA. Natural selection does not act directly on genes and can only select organisms from the gene pool

that exists for that organism (p. 397). It must be recognized that natural selection only works at the species level and that it cannot add the additional information so necessary for macro evolution to take place. Niles Eldridge, curator of the Museum of Natural History in New York City puts it this way, “*But natural selection per se does not work to create new species.*”<sup>1</sup>

On page 382 the authors extrapolate their statement quoted in the first of this section to say that descent with modification and common descent produce, “*A single ‘tree of life’ that links all living things on Earth.*” This conclusion is inconsistent with the facts of natural selection and the fossil record. It ignores the gaps in the fossil record. The late Steven J. Gould of Harvard concurred when he said, “*The extreme rarity of transitional forms in the fossil record persists as the trade secret of paleontology. The evolutionary trees that adorn our textbooks have data only at the tips and nodes of their branches, the rest is inference, however reasonable, not the evidence of fossils.*”<sup>2</sup>

At the bottom of page 381 the statement is made that “*As a result, species today look different from their ancestors. Each living species has descended, with changes, from their ancestors.*” This statement is misleading since there are many fossils that were once thought to be extinct but have been found alive today. The table below shows a small portion of organisms that have gone through so little change over millions of years that they are still recognizable as the same as the fossils. The above statement therefore is not true as a generalization. Paleontologist Dr. Joachim Scheven claims to have started a museum in Hagen, Germany where he has accumulated almost two hundred examples of fossils that were thought to be extinct but have been found alive. He has a video out on the subject. Some of the more commonly referred to fossils are shown in this table.

ALIVE ORGANISM	YEARS PRESENT IN THE FOSSIL RECORD
Coelacanth	350 to 70 million years <sup>3</sup>
Horseshoe Crab	424 to 50 million years <sup>4</sup>
Lingula	510 to 430 million years <sup>5</sup>
Neoplina	600 to 385 million years <sup>6</sup>
Graptolites	570 to 360 million years <sup>7</sup>

## Homologous Structures Page 384, line 17

The textbook makes the statement, “*Homologous structures provide strong evidence that all four limbed animals with backbones have descended, with modifications, from common ancestors.*” Homology is one of the proofs proposed for macro evolution. The real question is whether things that look similar **necessarily** have the same origin. Would you consider the bones of the same color shown in Figure 15-15 (p. 384) as being similar if you were given all of them in a bag with no labeling? Upon close examination of the animal structures presented in the figure it should be noted that there are bones located in the same relative location on the limbs but this does not mean that they have the same bony heads and size. Examination reveals they are not similar after all. The bone lengths, diameters and knobby protrusion locations, shape and size are all different. The information in the DNA must be very different to direct the formation of each of these different bone structures.

To further confuse the picture, Sir Gavin deBeer, Director of the British Museum of Natural History, said back in 1971 that, “*Has Dobzhansky explained it when he stresses that there is no one to one relation between a gene and a trait, that evolution does not consist of independent changes of organs or traits; but what changes is the genetic system. Is this also why organs can be homologous in spite of the genes controlling them being different.*”<sup>1</sup> The genes reveal that just because a structure is serving a similar purpose in different animals **it may not have come from an identical gene** and therefore have the same ancestor. Even if the genes were similar it is inconceivable that the many mutations required to produce these differences could have occurred by random chance happenings. For instance, the divisions of the fertilized egg (zygote) up to the stage where a complete sphere is formed (blastula) in reptiles and mammals are so different that it is impossible to conceive of the idea that they descended from the same ancestor even though the forelimbs look similar (homologous).<sup>2</sup> Also, the fore limbs of the newt, lizard and man develop from different parts of the embryo.<sup>3</sup> There are so many instances where similar structures obviously do not mean descent from a common ancestor that biologists call these **analogous structures**. What is it about a structure which determines common ancestry? This ancestor is not named. Does it exist? There is no clearly defined set of guidelines so that, basically, the decision depends upon what the observer is attempting to prove.

Another consideration regarding similarity of structures is whether there is an alternative way to perform a needed function. How many different ways can an appendage like a leg that serves to support an organism be attached to an organism? The requirement that the appendage must have stiffness can only be done in a living organism by bone or cartilage located either in the appendage or on the outside such as insects have. Can you think of another way? Except for the way they are connected together, shouldn't the bones used for support look approximately the same?

## **Vestigial Structures Page 385**

Originally, there were thought to be approximately 180 vestigial organs in man. Slowly over the years the number of organs considered vestigial has been reduced to a handful so that present thinking is that a use will be found for these few remaining organs as science progresses. This makes it obvious that just because an organ appears to have no use does not mean that the use will not be discovered later.

Some have maintained that the human tail-bone is a vestige of another way of life. This is no longer a true statement. It is now known that the human tail-bone serves as an attachment point for muscles that allows humans to walk more upright than the primates.<sup>1</sup> Even the appendix was thought to be vestigial but the medical profession now knows that it plays a functional role in the immune system.<sup>2</sup>

## **Similarities in Early Development Page 385 and Figure 15.17**

In 1891, Ernst Haeckel produced a series of drawings of vertebrate embryos proposing that they represent a kind of tree of life<sup>1</sup> as the authors point out. The drawings supposedly showed that all vertebrates pass through all of its macro evolutionary history in arriving at its final state and therefore is a proof of macro evolution. He used the drawings to illustrate what he called the Biogenetic Law. Haeckel was such an enthusiastic evolutionist that he altered his drawings in order to make his point. These errors were discovered before he died and he was tried in a court by his fellow professors at the University of Jena in Germany and found guilty of fraud.<sup>2</sup>

Even though it has been known for almost one hundred years that the drawings of Haeckel and the Biogenetic Law are not true very little effort was made to find out exactly what the facts are. Michael Pitman in 1984 reported <sup>3</sup>, “*Had he (Haeckel) started at the logical place, the zygote, he would have realized that different classes of egg differ greatly in yolk content, size and shape, cleavage patterns, blastula, and in the organization which prepares them for gastrulation. Haeckel’s series begins at the point when these diverse early stages converge, just before organ formation. This seems, for reasons unknown, to be the only tolerable intermediate stage. Thereafter, divergence again occurs into the diverse adult types.*” In the middle 1990's Dr. Michael Richardson of St. George's Medical School conducted a large scale investigation to determine the facts. He found that Pitman was right and that there was little resemblance between Haeckel's drawings and what he found. What he did find was that **some** embryos “*pass through an intermediate stage in which some of them superficially resemble each other (Haeckel's first stage)*” <sup>4</sup> as reported by Pitman and shown in Figure 15.17. It is important to recognize that this one appearance of similarity is true for this case only and indicates nothing since the embryos are very different for earlier and later development stages. Based upon this fact the similarity between the chicken, turtle and rat embryo shown in the figure is a gross misrepresentation of the facts.

The textbook author is misleading in the figure and its statement, “*In their early stages of development, chickens, turtles, and rats look similar, providing evidence that they shared a common ancestry.*” Keith Thomson, Chairman of the Yale University Biology Department, said, “*Surely the biogenetic law is as dead as a doornail. It was finally exorcized from biology textbooks in the fifties. As a topic of serious theoretical inquiry it was extinct in the twenties.*” <sup>5</sup>

## CHAPTER 16

This entire chapter is devoted to various factors that affect and change organisms. This is properly called micro evolution. Nothing is presented that has any bearing on macro or molecules to man evolution. All of the changes and methods of change yield only new species. In simple words, all of the lizards are still lizards (p. 397), the new beetle species are still recognizable as the same type of beetle (p. 400), the mutated bacteria are still the same in their effect on humans and close enough to the original bacteria to be called by the same name (p. 403), the squirrels are both recognized as squirrels (p.405), and Darwin’s finches are all recognizable as finches (p. 408).

## CHAPTER 17

### Fossils and Ancient Life Page 417, paragraph 2

The textbook says, “*The fossil record reveals a remarkable fact: Fossils occur in a particular order.*” These statements refer to the geologic column which is given in Figure 17-5 on page 421 of the text and are supposed to be proof of macro evolution. There are, however, many facts from the geological record that tend to challenge this. One of these is the fact that many gaps exist in the fossil record (see topic that follows this one). Are these gaps real? Darwin was aware of this problem when he wrote, “*Why then is not every geologic formation and stratum full of such intermediate links? Geology assuredly does not reveal any such finely graduated organic change, and this is perhaps the most obvious and serious objection which can be urged against the theory [of macro-evolution].*” <sup>1</sup> Professor Stephen J. Gould of Harvard University confirmed Darwin's doubts are still valid when he stated, “*All paleontologists know that the fossil record contains little in the way of intermediate forms; transitions between major groups.*” <sup>2</sup>

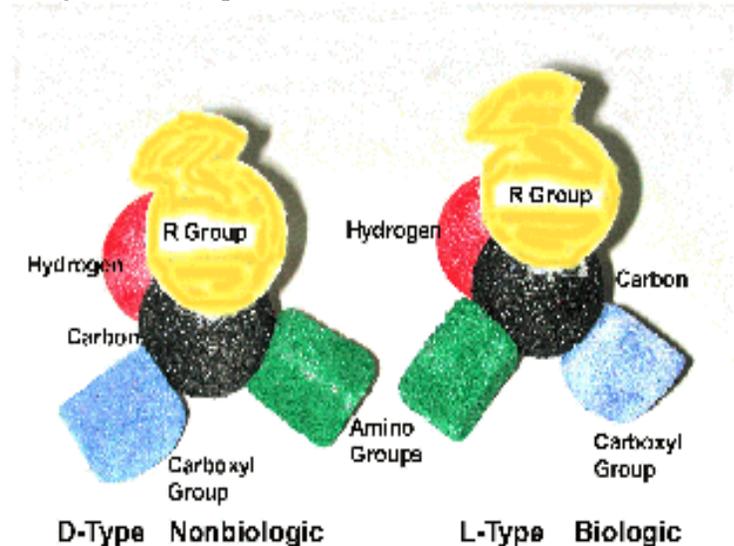

**Thinking Critically:** In view of the facts just quoted is the statement, "The fossil record tells a Story of Evolution" a reasonable one? Explain.

## Earth's Early History and The Origin of Life Page 421

In order to bring this discussion of the origin of life into correct perspective several facts must be recognized and kept in mind:

**Figure 1. Amino Acid Types**

amino acids occurring naturally only 20 are found in living organisms and are called biologic amino acids. This means that the vast majority of amino acids are classified as non-biologic. If one of the non-biologic amino acids joins with one of the 20 biologic amino acids, the result is a compound that is not useful for biologic purposes.

(2) To further complicate the situation, the exact order in which the Hydrogen atom, the Amino Group, the Carboxyl Group and the R Group join to the central carbon atom determines whether the amino acid formed can be used in forming a biologic protein. Amino acids are optical isomers which fall into two structural types --- dextro-rotary (D type) and laevo-rotary (L type). The L and D type molecules are identical chemically but are mirror images of each other just as our hands are. Notice that if the R Group and the H atom are taken as a reference by putting the H atom farthest from to the observer as shown in Figure 1 there are only two different ways the Amino and Carboxyl Groups can join the carbon atom - the Amino Group is either on the left or right of the reference. Only the order shown on the right of Figure 1 above (Amino Group to the left of the line proposed above) is used in forming a biologic protein. Very rarely are D amino acids found in living organisms.<sup>2</sup>

(3) It is important to recognize that the L and D amino acids like that shown in Figure 1 above occur in equal numbers in nature but no known life forms use both types of amino acids.<sup>3</sup> In forming a polypeptide the amino acids join to each other by the Amino Group joining the Carboxyl Group. Since these are common to all amino acids this means that there is no preferential connections of biologic verses non-biologic amino acids in forming poly-peptides. As shown above the difference between the L and D molecules is that the Carboxyl Group and the Amino Group swap places on the central carbon atom. In

(1) A carbon atom, an essential part of an amino acid, has four bonding sites. In forming an amino acid four different elements or compounds join to a central carbon atom as shown in Figure 1<sup>1</sup> a Hydrogen atom, a Carboxyl Group (COOH), an Amino Group (NH<sub>2</sub>) and an R Group which is a Carboxyl/hydrogen based unit. The composition of the R Group determines the particular characteristics of the amino acid and therefore its name. Note that the R Groups are very rarely symmetrical about an axis. The mock up shown in Figure 1 below shows this. The number of compounds that can join to the carbon atom at this spot is very large. Estimates are as high as several thousand. In each case the result is called an amino acid. Of all the possible

each resultant molecule the chemical equation is the same even though the shapes of the molecule are different. This is most easily understood by looking at Figure 1 and connecting the Carboxyl and Amino Groups together. This makes the R Groups point in the opposite directions with respect to the polypeptide chain so that the shapes are different.

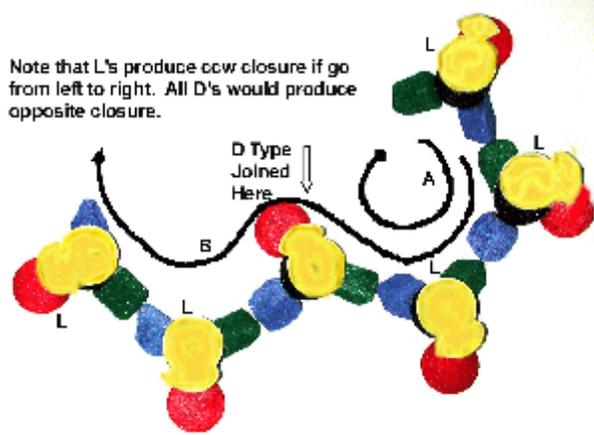

Figure 2. Effect of Introducing a D molecule into an L molecule chain

(4) If only L amino acids are connected in a chain they form a helix as shown by line “A” in Figure 2. If a single D amino acid is connected into a chain of L amino acids the resultant protein becomes non biologic. Note that not only is the R Group (yellow color) in the opposite direction from that of the L molecules but the shape of the polypeptide has also changed from the closed circular pattern of an all L chain to the shape shown by line “B”. If a single D type molecule gets into the chain of “L’s” the shape of the molecule has changed even though the chemical equation is the same. It is very important to recognize that the shape of a molecule determines how it will interact with other molecules. Dr. Mader points this out in her Biology textbook when she

says, “Shape is very important in determining how molecules interact with one another” and “Once a protein loses its normal shape it is no longer able to perform its usual function.”<sup>4</sup>

If a L type sugar were introduced into a chain of D sugars in the DNA strand it would not be able to coil without causing a tangle as illustrated by line “B”. This would be a fatal mistake.

(5) It is also known that nucleotides (DNA) are formed from a deoxyribose sugar molecule bonded to a phosphate molecule and a nitrogen base. RNA has ribose sugars in the place of deoxyribose sugars. The sugars in these nucleotides also occur in L and D type molecules. The arrangement of the sugars in the DNA ladder is shown below in Figure 3. (More details are given in the chapter on DNA.) Two different bases join to form a base pair and make a ladder rung.

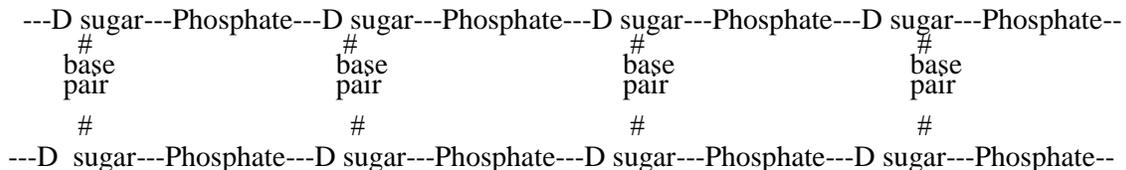

Figure 3. DNA Structure

How proteins formed originally with only L type amino acids and how sugars in the nucleotides (DNA and RNA) formed originally with only D type sugars is an unanswered question. This is particularly puzzling when it is remembered that L and D type sugars occur in equal numbers naturally and show no preference in uniting with phosphates. The same holds true for amino acids. A human chromosome consists of about 65 million base pairs on average which means that there are 130 million D type sugars in the DNA of one chromosome. The human genome contains 6,400,000,000 D type sugars.. Logically, half of these should be L type sugars but there are none. How could this have come about?

**Think Critically:** What do the L and D type molecules and the great number of possible amino acids do to the origin of life concept? Support your answer.

## Early Atmosphere Page 423

It is instructive to consider this and the next topics regarding the origin of life even though the previous discussion indicates molecular evolution is impossible.

In the world as it presently exists, life could not have evolved. Why? The presence of oxygen in the atmosphere precludes the formation of amino acids and the formation of polypeptides, proteins, ATP, nucleic acids in DNA and lipids. <sup>2</sup> Oparin attempted to solve this problem by proposing that if the atmosphere contained water vapor, hydrogen, methane and ammonia without any oxygen then energy from the sun and lightning would cause amino acids that would drop into the oceans and form a primordial soup from which life might have evolved.

**Think Critically:** What effect does the L and D problem have on this hypothesis?

Oparin did not include oxygen as an atmospheric gas because amino acids react readily with oxygen to form non-biologic compounds. His hypothesis led to the Miller- Urey experiments. There is, however, abundant evidence that oxygen was in the early atmosphere. Miller-Urey did prove by their experiment that the gases Oparin listed (methane, ammonia, hydrogen and water vapor) can be made to form amino acids (see next section). Most of the amino acids formed were not biologic. This makes the formation of a biologic compound impossible for reasons given in #4 below. Some more of the problems regarding the origin of life under this hypothesis are:

1. The geologic evidence indicates that the necessary atmosphere **without any oxygen** was **not** present. Many primordial sediments contain red minerals which are metallic compounds of oxygen indicating oxygen was present at the time of their formation. There is geologic evidence that the earliest rocks (dated at 3.7 b.y.) existed in an oxygenic atmosphere <sup>1</sup> so that the formation of amino acids in any significant concentration in the atmosphere and therefore in the ocean was not possible.<sup>3</sup>
2. Ultraviolet light breaks down the Oparin gases methane and ammonia, two of the three necessary building blocks of amino acids. The concentrations of these building blocks would have been reduced quickly to such a low level that they could not have played an important part in amino acid formation because the no oxygen hypothesis implies there was no ozone layer to reduce the ultraviolet intensity.
3. Ultraviolet light breaks down water, the third building block of amino acids, into oxygen and hydrogen. The presence of oxygen minimized the formation of any amino acids in the atmosphere.

These first three problems point out that any significant amino acid concentration in water could not come from the reaction of gases in the atmosphere. Even if amino acids could somehow be formed in a pool, lake or sea there are factors such as those listed below that make the formation of life unlikely. Consider the following problem areas:

4. There are two structural types of amino acids and sugars as discussed earlier--- dextro- rotary (D type) and laevo-rotary (L type). Whenever amino acids and sugars are being formed these two types are formed in equal numbers. No known life forms use both types of amino acids <sup>4</sup> and sugars. Both types of molecules will easily combine chemically with each other but only one of the wrong type of amino acid in a protein or sugar in the DNA will make it biologically useless from a functional viewpoint as pointed out earlier. The proteins of living organisms are made up of L type amino acids and the DNA strands from D type sugars. The duplication process of the cell assures use of only the right type of molecule. There is no other known process for separating and isolating L and D molecules. DNA produces tRNA which promotes the synthesis of L type proteins. There is no evidence that such a

separating mechanism was present until the first replicating life form came into existence.

5. Water is a diluting and reacting agent so the question must be answered as to how the amino acids can be concentrated to form polypeptides (chains of amino acids), proteins and, ultimately, organisms. The evaporating pool hypothesis, that evaporation will concentrate the amino acids, has the problem that some of the compounds necessary for protein synthesis evaporate<sup>5</sup> along with the water. Insulin, the smallest

protein, requires fifty one L type amino acids (17 different types). It is inconceivable that this many amino acids could be assembled on a molecular basis without the detrimental effects of water, D type or other type of amino acids or other non-biologic compounds interacting. Even if insulin is obtained this does not verify that evolution could take place because many more proteins are needed to have even the simplest living organism.

6. Natural selection only takes place in living organisms.

7. Amino acids are quick to combine with other compounds, including those from which they were formed, to form non-biologic compounds.

8. When two or more amino acids unite by the addition of energy to form a polypeptide, a water molecule is produced. This water molecule must be removed immediately because it will unite with the polypeptide. This means that the polypeptide is not stable unless the water is removed.<sup>6</sup> How can the water be removed when everything is in water. Ferris states this scientifically as,<sup>7</sup> *"But it has not proved possible to synthesize plausibly pre-biotic polymers this long (30 to 60 monomers) by condensation in aqueous solution, because hydrolysis competes with polymerization."*

9. Biochemical compounds tend to break down (decay) when not combined within a living organism. When living organisms die they decompose back into their simplest molecular components. The chemical tendency is away from life.<sup>8</sup> Thus even if a protein were formed it would not have been stable and would not have waited around for a spontaneous combination at some later time with other proteins.

## The Miller Experiment Page 424

The famous Miller-Urey experiment supposedly proved that life could have evolved. The apparatus is shown in Figure 17-8 on p. 424. One of the problems of this experiment was that the experiment produced both D and L type amino acids plus other non-biologic amino acids and polymers which were capable of reacting with the desirable biologic amino acids to produce non-biologic compounds.<sup>1</sup> Miller had to use a trap to isolate the products of his experiment and keep them from getting back to the original gases since the biologic amino acids formed would react readily with the excess gases and form non-biologic compounds. As necessary as it is, there is no mechanism in nature that can perform this needed isolation.

Their experiment came up with a total of only 10 biologic amino acids and 25 non-biologic amino acids, sugars and other compounds all mixed together. Insulin, one of the smallest of proteins, consists of 51 amino acid bonds and requires 17 different biologic amino acids. This simplest of proteins could not have been formed had there been nothing but the Miller biologic amino acids present. Other scientists<sup>2</sup> have done similar experiments with other sources of energy and formed many other biologic and non-biologic compounds but with similar results. Still other scientists have devised experiments which have produced still other compounds in living organisms. All of the cited experimenters results still involve L and D amino

acids and sugars plus other non-biologic amino acids and sugars so that the peptides formed are **not** indicative of life.

### **RNA Chain Formation Page 425**

As discussed earlier an RNA nucleotide consists of a base, a phosphate and a ribose sugar. The sugar can be in either the L or D form which considerably complicates the problem because only D or right handed sugars are present in living organisms. If a left handed ribose sugar appears in the chain then the RNA chain that might be formed is non-biologic. RNA chains have been observed to form as reported in the text but the real question is whether the initial conditions of the experiment truly represent conditions that would actually occur in a real life situation. It should also be recognized that chains of RNA that may be able to make copies of themselves are of no use unless they are able to make a biologic protein. The formation of a biologic polypeptide is of no consequence compared to the complexity of the first living organism.

### **Polymers Evolve Page 421**

The origin of life is discussed in such a manner that the textbook reader might believe that it was very simple and obvious. Nothing could be further from the truth. The rest of chapter 17 discusses the appearance of the different organisms as though man came about through the random assembly of many chemical compounds. There is no clear evidence that macro evolution has ever occurred when all of the previously cited facts are considered. The evidence is that it is impossible.

It is very easy to over simplify the idea of early life being primitive. The complexity of even the simplest life form is far from simple or primitive. As mentioned earlier one of the smallest prokaryotes, a mollicute or H-39 strain of mycoplasma (a bacterium) consists of 640 proteins whose average length is 400 amino acid bondings.<sup>1</sup> This means that it has 256,000 amino acids arranged in a very specific order. These amino acid bonds are coded in the DNA by means of 768,000 base pair bondings in a specific order and 1,536,000 sugar-phosphate pairs. If we add all of this together, we find that there are 4,864,000 individual chemical entities that must come together to form this "simple" bacterium (2x768,000 bases+1,536,000 sugars+1,536,000 phosphates+ 256,000 amino acids). Under ideal conditions, the odds of this many amino acids coming together in the right order are approximately the same as winning the Power Ball Lottery every week for the next 640 years. This neglects the L and D factors and other chemical compounds. How could this have happened accidentally? The step from inanimate organic compounds to a living organism is beyond man's ability to create.

It is further noted in the textbook that even though science has demonstrated other ways in which vital organic compounds might have been formed there is a vast gap between the forming of individual compounds and their assembly into the precise order necessary to obtain a living organism. As just stated, the H-39 mycoplasma has 4,864,000 compounds which have to be assembled in a precise way. This assumes there are no wrong L or D amino acids or sugars, no non-proteinous amino acids and other compounds such as were formed in the Miller-Urey experiments present. The addition of these unusable compounds greatly increases the already astronomical odds that organic compounds did not form spontaneously so that the Miller-Urey experiment has added additional problems for the evolutionist.

Recent experiments concerning the formation of polypeptides do not enhance the chances of macro evolution taking place unless the polypeptide is one that can be used in the particular organism. If it cannot be used then it is only making macro evolution less likely since it introduces an additional non-usable compound. If it is usable then it must be included in exactly the right place in the protein being formed - a very unlikely scenario.

## The Unbreakable Cycle

There is an unbreakable cycle in all cells and bacteria that makes any possibility of macro evolution coming about impossible. Part of the problem is that DNA by itself is useless unless the information can be read and acted upon. Another problem is that a cell without any DNA cannot duplicate itself and so does not lead anywhere. The fact that the mechanisms (enzymes) for duplication of cells and reading DNA is contained in the organism but the instructions on how they are to operate and how to form these mechanisms is in the DNA poses another difficulty. In other words, if the reading enzymes somehow came into existence without something to read (the DNA) plus instructions on what to do with the information obtained, they would be useless. They should have been eliminated according to standard evolutionary theory. In a similar manner, what good are the replication enzymes if operating instructions are not present. All of this information is in the DNA but serves no purpose by itself without some means to read it. The net result is that the DNA and the rest of the organism had to form at the same time. Any one by itself is a dead end. This means that the formation of the first living organism could not have occurred in steps. There is no theory of evolution which can account for the origin of biological structures which have multiple interdependent parts. Darwin recognized this for living organisms when he said, "*If it could be demonstrated that any complex organ existed which could not possibly have been formed by numerous, successive, slight modifications, my theory would absolutely break down.*"<sup>1</sup> If this is true for living organisms it is also true for nonliving organisms where natural selection does not function. There is no known way for origin of life theories to account for the origin of the first functional genetic code in a living cell.<sup>2</sup>

**Thinking Critically:** If all of modern science and technology have been unable to create life, are we to believe it happened by purely natural processes? Support your answer.

## Cambrian Fossils Page 430 and 746

The Cambrian Explosion is one of the mysteries of geology in that, as the authors state, *most animal phyla evolved*. More phyla have been discovered in these strata than exist now. The real problem is that these organisms seem to appear suddenly without any ancestors. Richard Dawkins, author of *The Blind Watchmaker*, puts it this way, "*...the Cambrian strata of rocks, vintage about 600 million years, are the oldest in which we find most of the major invertebrate groups. And we find many of them already in an advanced state of evolution, the very first time they appear. It is as though they were just planted there, without any evolutionary history.*"<sup>1</sup> For instance, the trilobite is an extremely complex organism with a segmented body and legs including a complex nervous system and one of the most complex eyes known. Science News puts it this way regarding trilobite eyes, "*...the most sophisticated eye lenses ever produced by nature.*"<sup>2</sup> There are trilobites in the pre-Cambrian strata but they show no signs of being related to the Cambrian trilobites. Even Charles Darwin recognized the Cambrian Explosion problem and had this to say on the subject, "*The case at present must remain inexplicable; and may be truly urged as a valid argument against the views here entertained.*"<sup>3</sup>

**Think Critically:** Is this what you would expect if macro-evolution were true?

## Dinosaur to Bird Evolution Page 432 and 807

The authors say on page 432, "*Since the 1990's, scientists working in China have found evidence for this hypothesis in other fossils that have the skulls and teeth of dinosaurs but the body structure and feathers of birds.*" The evidence found was named Protarchaeopteryx and Caudipteryx. The two strata that they were

found in are reported dated at 120 and 136 million years and the fossil birds were reported to be “more primitive than Archaeopteryx.”<sup>1</sup> The difficulty is that Archaeopteryx, which is recognized as a true bird in biology textbooks,<sup>2</sup> is dated at 150 million years old. These so called ancestors of the bird are about 20 million years younger than the parent. How can they be called intermediates? Can a parent be younger than the children?

2. *Modern Biology.* Holt, Rinehart and Winston, 2002, p.862.

## **Macroevolution Page 435**

The authors state, *Six important patterns of macroevolution are mass extinctions, adaptative radiation, convergent evolution, co-evolution, punctuated equilibrium, and changes in developmental genes.* There is no doubt that these factors cause changes in the populations of the different organisms alive at the time but there is no evidence that this happened on anything except the species level which is micro evolution. All of the examples cited are examples of micro evolution. No proofs of macroevolution are presented.

## **Punctuated Equilibrium Page 439**

The student should notice that gradualism and punctuated equilibrium are both presented as hypotheses. The author does a good job of describing each hypothesis. Only one more factor needs to be made clear. The need for the punctuated equilibrium hypothesis has been brought about by the recognized gaps in the fossil record. The Harvard paleontologist Stephen J. Gould, who along with Niles Eldridge and Steven Stanley originated the punctuated equilibrium hypothesis, said, *“The extreme rarity of transitional forms in the fossil record persists as the trade secret of paleontology. The evolution trees that adorn our textbooks have data only at the tips and nodes of their branches, the rest is inference, however reasonable, not the evidence of fossils.”*<sup>1</sup>

The authors of the punctuated equilibrium hypothesis proposed it to explain the gaps in the fossil record at the species level. Note that this hypothesis has no factual evidence supporting it. The fact that there is no supporting evidence (the gaps) is the proof of the hypothesis. Contrary to the punctuated equilibrium authors wishes, some have extended the hypothesis to include the gaps at higher levels.

Two of the major objections to the hypothesis are:

1. The lack of evidence as established by the gaps. The feeling is that it would be dangerous to let the idea of lack of evidence as proof get started in science.
2. There is no plausible mechanism or explanation for the genetic changes that occur.

Figure 17-25 uses the supposed horse evolution as an example of gradualism and punctuated equilibrium. It should be recognized that the familiar pictures of the supposed evolution of the horse are found only in museums and textbooks. They are not substantiated by the fossil record. David Raup, Curator of the Museum of Natural History, where approximately 20% of the world’s fossils are housed, comments,<sup>2</sup> *“.....some of the classic cases of Darwinian change in the fossil record, such as the horse in North America, have had to be discarded or modified as a result of more detailed information.”* Note that this comment was made back in 1979.

2. Raup, David, *Conflicts Between Darwin and Paleontology,* Field Museum of Natural History Bulletin, Vol. 50, No.1 (1979), p. 25.

## **Developmental Genes and Body Plans Page 440**

Refer back to section 5 of Chapter 12 of this text (p.312) and the section on mutations on page 1 of this addendum. It is significant that all of the mutational efforts and studies on the fruit fly have never produced anything but a fruit fly. There is absolutely no evidence for macro evolution in these experiments. Remember that mutations do not add additional coherent information to the DNA. The conclusion is that wherein the “hox” genes have the capability given by the authors this does not provide any evidence for

macro evolution.

## CHAPTER 32

### Human Evolution Pages 834 - 841

The textbook author states on page 834 that "*Humans and other primates evolved from a common ancestor that lived more than 65 million years ago.*" The entire section 32-3 is devoted to pointing out similarities between humans and other primates. Just because two animals look somewhat alike and have similar characteristics does not necessarily mean they came from a common ancestor. This is a repeat of the homology argument discussed earlier.

Consider the following facts in deciding whether or not man and chimpanzee "*evolved from a common ancestor.*" A recent article in the Proceedings of the National Academy of Sciences suggests that there is approximately a 5% difference between the DNA of chimpanzees and humans.<sup>1</sup> This information was obtained by comparing approximately 1% of the genome and considered substitutions, insertions and deletions. As more of the genome is considered the difference has risen to 7.7%<sup>2</sup> and 13.3%. It has even been estimated to be as high as 20%.<sup>3</sup> The much publicized number of 1.4% was obtained by considering only substitutions.

Even the 5% difference amounts to a staggering amount of information in the DNA. If the human and chimpanzee genomes are considered to have the same number of base pairs, (3,200,000,000) in spite of the chimp having 2 more chromosomes than the human and 10% more DNA,<sup>4</sup> the 5% amounts to 150,000,000 bases. This is the amount of information contained in a book whose thickness is equivalent to about 30 books such as this textbook if it contained nothing but full pages of print from cover to cover. If this much information difference exists in the DNA between the chimpanzee and the human the difference between man's ancestor and man **must be much larger**. It is completely inconceivable that this much coherent information could have been accidentally changed in the DNA of a member of the ape family to get man when the mutational problems discussed earlier are considered. If the transition from ape to man is to be accomplished by mutations, it is apparent that there should be plenty of fossil evidence. Where is the fossil evidence?

**Think Critically:** If the chimp has 10% more DNA than a human how can it be said that there is only a 5% difference? Which of the differences given above is the most reasonable?

There is much disagreement over whether or not "Lucy" is in the ancestral lineage of man. Many reputable paleontologists maintain that she is only a pygmy chimpanzee similar to ones alive today. Paleontologist Adrienne Zihlman, University of California at Santa Cruz says, "*Lucy's fossil remains match remarkably well with the bones of a pygmy chimp.*"<sup>5</sup> Evolutionists such as Charles Oxnard, Sir Solly Zuckerman, William L. Jungers, Jack T. Stern, Jr and Randall L. Susman all concur.<sup>6-9</sup>

## Conclusions

What has been covered in this addendum should be kept in mind as one reads through the rest of the textbook. As stated at the beginning of this addendum the authors assume that macro-evolution is true and use this assumption to make unsubstantiated statements addressing the origin of different organisms. The reader should always keep in mind that macro-evolution cannot happen unless a change increases the information content of the DNA in a meaningful manner. This will help a person to determine whether or not a change is reasonable and/or possible.

Now that the end of this addendum has been reached several conclusions should be obvious such as:

1. It is misleading to use the term evolution without specifying whether it is micro or macro evolution being discussed.
2. Adaptation or micro evolution occurs at the species level and is provable using conventional scientific tests and principles. It is a fact.
3. The fact that adaptation of species (micro evolution) is true does not imply or prove that molecules to man evolution (macro evolution) occurs any more than the first cool days of October imply or prove that an ice age is beginning or because a person learns something from watching PBS for an hour imply or prove that watching PBS continuously will produce a genius. The major problems that Darwin recognized with his hypothesis are still true plus new ones as science has advanced. Some of these are:
  - Gaps in the fossil record.
  - Cambrian explosion
  - The fossilization process demands catastrophic happenings more violent than what we see today.
  - Similar genes do not necessarily produce similar structures.
  - How new meaningful information can be added to the DNA by random chance happenings.
  - Optical isomers preclude life evolving.
4. Other explanations for what is observed on earth should be examined.
